Human Health Risk Screening Evaluation for 690-N Ford Building (U)

SDD-2019-00030

April 2019

SAVANNAH RIVER SITE • AIKEN, SOUTH CAROLINA

HUMAN HEALTH RISK SCREENING EVALUATION FOR 690-N FORD BUILDING

BACKGROUND/SUMMARY

In June 2014, a human health risk screening evaluation for the 690-N Ford Building Soils and Concrete Samples was completed but it was never formally submitted as a regulatory document in support of the deactivation and decommissioning (D&D) strategy for this facility. The 2014 evaluation was completed in parallel with the *Characterization Report 690-N (Ford Building) and Ancillary Equipment and Facilities* (SRNS 2014). The human health risk screening evaluation using the 2014 screening results has been finalized as described in this document to support the demolition of the facility. In addition, this document presents the data that was collected as part of the 690-N Ford Building characterization effort as outlined in the Characterization Report (SRNS 2014) and draws risk screening conclusions from samples collected from the concrete slab and soils beneath the slab. The characterization plan for the 690-N Ford Building, discussed in Section 3.1 of the Characterization Report (SRNS 2014), states that the concrete floor slab and soils beneath the slab 0 to 30 centimeters (cm [0 to 12 inches{in.}]) will be sampled for liquid scintillation counting with tritium, polychlorinated biphenyls (PCBs), Resource Conservation and Recovery Act metals, volatile organic compounds (VOCs), semi-VOCs (SVOCs), and total halogens. This human health risk screening evaluation and the Characterization Report (2014) support the *Facility Decommissioning Evaluation for Building 690-N, Process Heat Exchanger Repair Facility* (SRNS 2019).

In summary, human health and contaminant migration screenings were performed on VOC, SVOC, PCB, inorganic anion, and radiological data from the 690-N Ford Building concrete slab and underlying soil. Constituents with concentrations that exceeded human health screening levels for soil and concrete are further evaluated in an abbreviated uncertainty (i.e., weight of evidence) discussion. Only PCBs (max in concrete = 15 parts per million [ppm]) and cesium-137 (max in concrete = 1.75 picocuries per gram [pCi/g]) are present in the 690-N Ford Building at levels that warrant concern with respect to human health.

DATA EVALUATION

Soil samples and concrete samples were collected from 21 locations at the 690-N Ford Building in February, March, and April 2014 as described in the Characterization Report (SRNS 2014). The samples from the concrete slab were collected from two intervals: 0- to 15-cm and 15- to 30- cm (0- to 6-in. and 6- to 12-in.); the soil samples were collected from 0- to 15-cm and 15- to 30-cm (0- to 6-in. and 6- to 12-in.) below the concrete slab. From a human health risk perspective, only the surface interval (0- to 15-cm [0 to 6 in.]) from the concrete slab offers a complete exposure pathway, but this evaluation conservatively considers data from all intervals. A comparison of sample results to human health screening levels was performed for VOCs, SVOCs, PCBs, inorganics, and radiological constituents. Metals were analyzed via the toxicity characteristic leaching procedure (TCLP) only; a total metals analysis was not performed. The following standards were used in the evaluation:

SOIL

Non-radiological	United States Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs), May 2014 (USEPA 2014)
Radiological	USEPA Preliminary Remediation Goals (PRGs), August 2010 (USEPA 2010)

CONCRETE

Non-radiological	10x the soil RSLs
Radiological	USEPA Surface PRGs (SPRGs) for radionuclides, 2-D external exposure, March 2011 (USEPA 2011)

Table 1 is a comparison of the maximum detected concentration of each analyte in soil and concrete to both the residential and industrial RSLs/PRGs that were available in 2014. Exceedances (shown in red font in the table) are further addressed in a streamlined uncertainty (i.e., weight of evidence) evaluation presented below. Tables 2 and 3 show the radiological and VOC results by sample location. Although the maximum detects are summarized in Table 1 and are considered in the RSL/PRG comparisons, these tables do not include the halides and polycyclic aromatic hydrocarbon (PAH) location specific information. All the data collected from the 690-N Ford Building, including the concrete and soil VOCs, SVOCs, PCBs, halides, TCLP, and

radiological data are shown in Table 4. The data in Table 4 is from the Environmental Restoration Data Management System (ERDMS) database.

One other clarification that should be acknowledged is that the Concrete and Soil Radscreen Analysis shown in Appendix A of the 2014 Characterization Report includes gross alpha, nonvolatile beta and tritium results that were conducted by Savannah River National Laboratory for offsite release/shipping purposes. The screening standards for shipping/transportation are higher than industrial/residential exposure, and as a result, the analyses are run with much higher detection limits than the detection limits required by the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) program. In contrast, the data screening in this report was performed using the results run to meet CERCLA screening levels (reported from Test America Laboratory) and therefore have much lower detection limits. Maximum detected concentration of gross alpha, nonvolatile beta and tritium for each sample are shown in Table 1 and the results for each of the concrete and soil sample locations are shown in Tables 2 and 3.

Constituents that exceeded the human health screening levels for soil and/or concrete are discussed below. These include 5 nonradiological constituents (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, Aroclor 1254, and Aroclor 1260) and 10 radiological constituents (cesium-137, tritium, protactinium-233, tin-126, actinium-228, bismuth-212, bismuth-214, lead-212, thallium-208, and potassium-40).

UNCERTAINTY DISCUSSION

Benzo[a]anthracene: Not detected in the soil media beneath the concrete slab. The maximum detected concentration (2,100 parts per billion [ppb]) in the concrete media exceeds the resident screening level (1,500 ppb). Using the maximum detected concentration yields a residential risk = 1.4E-06. There are no exceedances of industrial worker screening levels. Benzo(a)anthracene was detected in 1 of 21 surface concrete samples (0- to 15.2-cm [0- to 6-in.]) and 0 of 21 samples from the 15.2- to 30.4-cm (6- to 12-in.) interval. Benzo(a)anthracene is not recommended to be identified as a problem warranting action for human receptors because there is a low frequency of

detection (less than [<] 5 percent [%]) and the risk estimate is biased high (i.e., based on the maximum concentration).

Benzo[a]pyrene: Not detected in the soil media beneath the concrete slab. The maximum detected concentration (1,100 ppb) in the concrete media exceeds the resident screening level (150 ppb). Using the maximum detected concentration yields a residential risk = 7.3E-06. There are no exceedances of industrial worker screening levels. Benzo(a) pyrene was detected in 1 of 21 surface concrete samples (0- to 15.2-cm [0- to 6-in.) and 0 of 21 samples from the 15.2- to 30.4-cm (6 to 12-in.) interval. Benzo(a) pyrene is not recommended to be identified as a problem warranting action for human receptors because there is a low frequency of detection (<5%) and the risk estimate is biased high (i.e., based on the maximum concentration).

Benzo[b]fluoranthene: Not detected in the soil media beneath the concrete slab. The maximum detected concentration (2,000 ppb) in the concrete media exceeds the resident screening level (1,500 ppb). Using the maximum detected concentration yields a residential risk = 1.3E-06. There are no exceedances for the industrial worker scenario. Benzo(b)fluoranthene was detected in 1 of 21 surface concrete samples (0- to 15.2-cm [0- to 6-in.) and 0 of 21 samples from the 15.2- to 30.4-cm (6- to 12-in.) interval. Benzo(b)fluoranthene is not recommended to be identified as a problem warranting action for human receptors because there is a low frequency of detection (<5%) and the risk estimate is biased high (i.e., based on the maximum detected concentration).

Aroclor 1254: There are no RSL exceedances in the soil media beneath the concrete slab for either the resident or industrial worker scenarios. The maximum detected concentration (15,000 ppb) in concrete exceeds both the resident (2,400 ppb) and industrial worker (10,000 ppb) thresholds. Using the maximum detected concentration yields a residential risk = 6.3E-06 and an industrial worker risk =1.5E-06. Aroclor 1254 was detected in all of the concrete samples (42 total, 0- to 15.2-cm [0- to 6-in.] and 15.2- to 30.4-cm [6-to 12-in.]).

In addition, the Aroclor 1254 concrete sample results exceed the Applicable or Relevant and Appropriate Requirements (ARAR) concentration of 1 ppm for polychlorinated biphenyls (PCB) required for free release. For purposes of cleaning, decontaminating or removing PCB remediation

waste, cleanup levels are based on the kind of material and the potential exposure to PCBs left after cleanup is completed. USEPA has established a <1 ppm limit for PCBs in high-occupancy areas, and a <25 ppm limit for PCBs in low-occupancy areas.

Aroclor 1254 is a known waste stream at the 690-N Ford Building, and its presence is consistent with the historical use of the unit. PCBs were components of hydraulic fluid used in machine tools. Therefore, it is recommended that Aroclor 1254 be identified as a problem warranting action, with the following remedial action objective:

- Prevent residential and industrial exposure to Aroclor 1254 in concrete media that exceed the PCB ARAR of 1 ppm for free release and 1E-06 risk.

Aroclor 1260: There are no RSL exceedances in the soil media beneath the concrete slab for either the resident or industrial worker scenarios. The maximum detected concentration (5,500 ppb) in concrete exceeds the resident (2,400 ppb) threshold only. The residential risk estimate based on the maximum detected concentration = 2.3E-06. Aroclor 1260 was detected in all of the concrete samples (42 total, 0 to 15.2 cm [0 to 6 in. and 15.2 to 30.4 cm [6 to 12 in.]).

In addition, the concrete sample results exceed the ARAR concentration of 1 ppm PCB required for free release. For purposes of cleaning, decontaminating or removing PCB remediation waste, cleanup levels are based on the kind of material and the potential exposure to PCBs left after cleanup is completed. USEPA has established a <1 ppm limit for PCBs in high-occupancy areas, and a <25 ppm limit for PCBs in low-occupancy areas.

Aroclor 1260 is a known waste stream at the 690-N Ford Building, and its presence is consistent with the historical use of the unit. PCBs were components of hydraulic fluid used in machine tools. Therefore, it is recommended that Aroclor 1260 be identified as a problem warranting action, with the following remedial action objective:

- Prevent residential and industrial exposure to Aroclor 1260 in concrete media that exceeds the PCB ARAR of 1 ppm for free release and 1E-06 risk level.

Cesium-137(+D): Not detected in the soil media beneath the concrete slab. Concentrations in concrete (maximum = 1.75 pCi/g) exceeds both the resident (0.0625 pCi/g) and industrial worker (0.104 pCi/g) screening levels. Using the maximum detected concentration yields a residential risk = 2.8E-05 and an industrial worker risk =1.7E-05. Cesium-137 was detected in 9 of 21 surface concrete samples (0- to 15.2-cm [0- to 6-in.]), and 4 of 21 samples from the 15.2- to 30.4-cm [6- to 12-in.) interval.

Cesium-137 is a result of nuclear fission. It does not occur naturally in soil. However, cesium-137 is common in SRS background soils as a result of fallout from nuclear weapons testing. Maximum background concentration in SRS soils is 3.3 pCi/g and mean concentration is 0.142 pCi/g (WSRC 2006). However, its presence at the 690-N Ford Building is not due to atmospheric fallout, but is attributable to unit operations (i.e., servicing heat exchangers). Therefore, it is recommended that cesium-137 be identified as a problem warranting action, with the following remedial action objective:

- Prevent residential and industrial exposure to Cs-137(+D) in concrete media that exceeds the 1E-06 risk level.

Tritium: Concentrations in soil media (max = 45.1 pCi/g) exceed the residential (0.93 pCi/g) and industrial (1.27 pCi/g) PRG thresholds. These PRG threshold levels are driven entirely by the inhalation pathway (i.e., no external exposure). However, the soil media beneath the concrete slab does not offer a complete exposure pathway for human receptors. In the concrete media, a maximum activity of 182 pCi/g was detected. It was detected in all of the concrete samples (42 total, 0- to 15.2-cm [0-to 6-in.] and 15.2- to 30.4-cm [6- to 12-in.]). The 2-dimensional external exposure SPRG website does not publish a tritium screening level for this media because it is considered an incomplete exposure pathway. Therefore, it is recommended that tritium in soil or concrete media not be identified as a problem warranting action for human receptors at the 690-N Ford Building.

Protactinium-233: Four of 36 concrete samples had reported detections of protactinium-233 (Pa-233), which is a daughter product of the transuranic nuclide Neptunium -237 (Np-237); one of the four samples exceeded the resident and composite worker 2-D SPRGs for Np-237+D, with

a reported concentration of 0.234 pCi/g. If the Pa-233 detections are real, then Np-237 should also be detected at the same concentration. However, there were no Np-237 detections in any concrete or soil sample. Therefore, the reported results for Pa-233 are regarded as false positives and it is recommended that Pa-233 not be identified as a problem warranting action for human receptors at the 690-N Ford Building.

Tin-126: Two detections of Tin-126 (Sn-126) were reported in concrete, at concentrations of 0.96 and 0.91 pCi/g. Sn-126 is a fission product but is only about 1E-05 as abundant as Cs-137 in fission waste and should not be detectable in environmental samples. Sn-126 analyses are performed by gamma spectroscopy, but all three of its gamma peaks are subject to interference from naturally-occurring Thorium-234 (Th-234), Lead-214 (Pb-214), or Lead-212 (Pb-212). Therefore, the reported Sn-126 detections are regarded as false positives and it is recommended that Sn-126 is not identified as a problem warranting action for human receptors at the 690-N Ford Building.

Actinium-228, Bismuth-212, Bismuth-214, Lead-212, Thallium-208: Maximum concrete concentrations of these naturally-occurring radionuclides exceed the concrete 2-D SPRG for both resident and composite worker, and all maximum soil concentrations except Bi-212 exceed residential and industrial scenarios for soil. However, the maximum concentrations for soil and concrete at the 690-N Ford Building are below maximum SRS background concentrations for soil (WSRC 2006); therefore, the activities of these constituents are consistent with background values and it is recommended that Ac-228, Bi-212, Bi-214, Pb-212 and Th-208 not be identified as problem warranting actions for human receptors at the 690-N Ford Building.

Potassium-40: Every concrete sample had a concentration of naturally-occurring potassium-40 (K-40) which exceeded the concrete 2-D SPRG for both resident (0.152 pCi/g) and composite worker (0.266 pCi/g). In concrete, the maximum concentration was 18.3 pCi/g, and the average concentration was 14.1 pCi/g. These concentrations are typical for concrete which contains granite aggregate (University of Maryland 2007) which is the case for most concrete at SRS and in surrounding communities. These concentrations are considered background levels for concrete

with granite aggregate, and it recommended that K-40 not be identified as a problem warranting action for human receptors at the 690-N Ford Building.

CONTAMINANT MIGRATION ANALYSIS

In order to evaluate the possibility for unit constituents to migrate to the water table and impact groundwater at concentrations exceeding regulatory limits, the data were evaluated using the VZCOMML 4.0 spreadsheet (Rucker 2009). Maximum detections were input separately for soil and concrete, assuming a 15.2-meters (50-feet) thick vadose zone, and a Dilution/Attenuation Factor of 1. Results show that no constituents in soil or concrete are predicted to impact groundwater at concentrations exceeding Maximum Contaminant Levels/RSLs within 1,000 years.

CONCLUSION

Human health and contaminant migration screenings were performed on VOC, SVOC, PCB, inorganic anion, and radiological data from the 690-N Ford Building concrete slab and underlying soil. A number of constituent concentrations exceeded human health screening levels for soil and/or concrete. However, only PCBs (Aroclor-1254 and Aroclor-1260) and cesium-137 are present in concrete media at the 690-N Ford Building at levels to warrant concern with respect to human health. Although the RSL and PRG values have been updated since the 2014 characterization, there are no significant changes in the screening thresholds that would change the preliminary conclusions of this evaluation.
